National University of Singapore School of Computing CS1010X: Programming Methodology Semester II, 2016/2017

Mission 8 New IPPT

Release date: 06 March 2017 **Due: 09 April 2017, 23:59**

Required Files

- mission08-template.py
- ippt.py
- pushup.csv
- situp.csv
- run.csv

Background

Every year, able-bodied Singaporean males who are in or have completed compulsory military training (a.k.a. National Service) would have to participate in the Individual Physical Proficiency Test (IPPT). The IPPT is a physical fitness test meant to assess the fitness of our soldiers to ensure that our soldiers are physically fit in times of uncertainty.

In 2014, the Ministry of Defence introduced a new test format and scoring system for $IPPT^1$. The new IPPT consists of the following 3 stations:

- Pushup, which measures upper body strength
- **Situp**, which measures abdominal strength
- 2.4km Run, which measures cardiovascular fitness and lower body strength

A soldier participating in the IPPT will first attempt as many pushups and situps that they can do in one minute each. Depending on their age, they are given a points based on the number of repetitions they have completed. Next they have to complete a 2.4km run, and would be given a p depending on how fast they complete a run.

The final IPPT score is the sum of all the scores obtained at the 3 stations, it determines if they have passed or failed the IPPT. To reward and motivate soldiers to maintain a high level of fitness, a monetary reward is given for soldiers who have demonstrated a high level of physical fitness. The reward amount depends on the final score obtained, and can be broken down into Pass, Pass with Incentive, Silver, and Gold. This is known as the IPPT Award.

¹For more information on the new IPPT, please go to http://www.mindef.gov.sg/imindef/press_room/official_releases/nr/2014/jul/24jul14_nr.html#.VBUbTS6SzR1

In this mission, you will create an IPPT calculator, which would help our soldiers calculate their IPPT score and award, given their age, and score they attained at the various stations.

This mission consists of **5** tasks, and a bonus task.

IPPT Data

The IPPT scoring criteria is provided to you in 3 different files:

Pushups: pushup.csvSitups: situp.csv2.4km Run: run.csv

Pushup / Situp

Pushups and Situps in the IPPT are scored in terms of the number of repetitions that a soldier can do in one minute. pushup.csv and situp.csv lists the scores that a soldier of a certain age will obtain if they managed a particular number of repetitions.

The first row describes the number of repetitions, whereas the first column lists the age of the soldier.

From the file situp.csv, we observe that an 18 year-old who did 10 situps would get 0 points (green box), whereas a 40 year-old who did 10 situps would get 3 points (yellow box).

18	_	A	В	С	D	E	F	G	Н	1	J	K	L	M

2.4km Run

The 2.4km run in the IPPT is scored based on the timing a soldier takes to complete a 2.4km run. To simplify things, we will represent the time of the run in seconds. run.csv lists the score that a soldier of a certain age will obtain if they complete the run under a particular timing.

The first row describes the time in seconds, while the first column lists the age of the soldier.

A different score is given whenever there is a timing difference of 10 seconds. From the run.csv file, we observe that an 18 year-old who ran 08:30 (510 seconds) or faster would get 50 points and one who ran between 08:31 (511 seconds) and 08:40 (520 seconds) inclusive would get 49 points.

The data file shows the scores for the timing between 510 seconds to 1100 seconds. Naturally, a timing less than 510 seconds would get 50 points, and a timing exceeding 1100 seconds would get 0 points.

Administrivia

The following functions have been provided to you:

- create_ippt_table(pushup_table, situp_table, run_table)
- get_situp_table(ippt_table)
- get_pushup_table(ippt_table)
- get_run_table(ippt_table)

Table Data Structure

To help you manipulate and access the data in a tabular fashion, we have provided an implementation of a table data structure which would help you access the scores in the IPPT table.

The functions that are provided for the table data structure:

- create_table(data, row_keys, col_keys)
- access_cell(table, row_key, col_key)

create_table takes in 3 parameters. The first parameter, data is a tuple of tuples, which contains the table of data. The second parameter, row_keys is the tuple of keys associated to each row, and the third parameter, col_keys is the tuple of keys associated to each column.

As an example, consider the following table:

The following code sample illustrates how to represent the above data in Python using our own table data structure:

S/N	Name	Gender	Age	Course
1	Wai Hon	M	23	Business Analytics
2	Yang Shun	M	25	Computer Science
3	Xiangxin	F	18	Computer Science
4	Soedar	M	25	Computer Science

access_cell, is a general accessor which would retrieve a particular cell from a table given a row_key and a column_key. Compare the returned value of the execution of the access_cell functions below with the table above.

```
access_cell(user_table, 1, "Course") # Business Analytics
access_cell(user_table, 2, "Age") # 25
access_cell(user_table, 3, "Name") # Xiangxin
access_cell(user_table, 4, "Gender") # M
```

Task 1: Read Data (4 marks)

Implement read_data, a function that would read the input data file, and return a table of scores for a particular station.

```
situp_table = read_data("situp.csv")
pushup_table = read_data("pushup.csv")
run_table = read_data("run.csv")

# Situp score of a 24 year old who did 10 situps.
access_cell(situp_table, 24, 10)  # 0

# Pushup score of a 18 year old who did 30 pushups.
access_cell(pushup_table, 18, 30)  # 16

# Run score of a 30 year old who ran 12 minutes (720 seconds)
access_cell(run_table, 30, 720)  # 35

# Since our run.csv file does not have data for 725 seconds, we should
# get None if we tried to access that cell
access_cell(run_table, 30, 725)  # None
```

Award Name	Award String	Total Score
Fail	"F"	≤ 5 0
Pass	"P"	> 50
Pass with Incentive	"P\$"	> 60
Silver	"S"	> 70
Gold	"G"	> 80

Task 2: Custom Accessors (6 marks)

The default accessor function, access_cell, is a general accessor which retrieves a particular cell given a row_key and a column_key. As such, it is not aware of the type of data the table contained, and would not return the correct score if the column_key does not exists in our data.

We would like to create a custom accessor for each station. When the column_key does not exist, the cell with the closest column_key value will be returned. For example, pushup_score(pushup_table, 18, 61) returns 25 which is the score in cell (18, 60) because 61 doesn't exist and the closest column is 60.

Both push up and sit up tables have column keys ranging from 1 to 60. The run table has column keys ranging from 510 to 1100. Moreover, the score data are in an interval of 10 seconds, we are not able to access the run score for a timing that falls within the 10 seconds interval. For example, a 30 year old male who has a run timing of 735 seconds will be considered under the band of 740 seconds and will get 34 points (timing is rounded up to the nearest band). Using a custom accessor would allow us to retrieve the correct score.

Create new accessors for each of the stations. You may assume that the inputs are guaranteed to be positive integers and that all given row_key will be in the valid range.

Situp and Pushup

```
situp_score(situp_table, 24, 0) # 0
pushup_score(pushup_table, 18, 61) # 25
pushup_score(pushup_table, 18, 70) # 25
```

2.4km Run

```
run_score(run_table, 30, 720) # 35
run_score(run_table, 30, 725) # 35
run_score(run_table, 30, 735) # 34
```

Task 3: Calculate IPPT Award (2 marks)

An IPPT Award is awarded based on the total score that a soldier has obtained for all the 3 stations. We will use the following table to determine the IPPT Award.

Define a function, ippt_award, which will return the Award String for a given IPPT Score

```
ippt_award(50) # F
ippt_award(51) # P
```

Task 4: Calculate IPPT Results (2 marks)

We can now calculate the IPPT score and the qualifying award of a soldier's test attempt. The result consists of both the total points and the grade awarded, and is represented as a tuple of (Total IPPT Score, IPPT Grade).

Implement the function <code>ippt_results(ippt_table, age, pushup, situp, run)</code>, which will calculate the total IPPT score and award given the soldier's age, number of situps, number of pushups, and 2.4km run timing.

Task 5: Training Hard (4 marks)

Wai Hon's IPPT is coming soon, and he would like to determine the best training program that he should embark on in order to obtain the highest possible IPPT score before the IPPT test. A training program is characterized by the improvement that one can obtain in each of the IPPT stations, namely:

- rate_pushup: Number of days it will take to increase the pushup count by 1
- rate_situp: Number of days it will take to increase the situp count by 1
- rate_run: Number of days it will take to decrease 2.4km run timing by 1 second

By following a training program, improvements will be made in **all** 3 stations. For instance, if rate_pushup is 1, rate_situp is 1, and rate_run is 1, after 10 days of following the training programme, Wai Hon will improve his situp count by 10, pushup count by 10, and his 2.4km run timing by 10 seconds.

Implement the function make_training_program(rate_pushup, rate_situp, rate_run), and returns a new function which accepts 5 parameters, age, pushup, situp, run, and days.

The returned function will then return the number of pushups, situps, and the 2.4km run timing that can be achieved at the end of the specified number of days, and also the improved IPPT score.

```
program_a = make_training_program(7, 3, 10)
program_a(ippt_table, 25, 30, 25, 820, 30) # (34, 35, 817, (61, 'P$
```

Bonus: Skip Leg Day (2 bonus marks)

In Task 5, by following the training programme, we are able to gain improvements in all the stations daily. We will tweak the question slightly for this bonus task.

Suppose that we are not able to gain daily improvements for all the stations, and that we have to focus on improving our score for each station one at a time. What is the best possible IPPT score we can obtain at the end of a specified number of days?

You should assume that you can improve on another station only after you have gained at least one unit of improvement in a particular station.

Hint: Have you solved a similar problem before? :)

Note: Depending on your implementation, you might get a different number on situp, pushup, and 2.4 km run timing. However, the IPPT score and grade should be the same as the sample output.

Note: The full score is capped at 18 marks for this mission.

```
tp_bonus = make_tp_bonus(7, 3, 10)
tp_bonus(ippt_table, 25, 20, 30, 800, 30)  # (20, 40, 800, (58, 'P'))
tp_bonus(ippt_table, 25, 20, 30, 800, 2)  # (20, 30, 800, (52, 'P'))
```
